

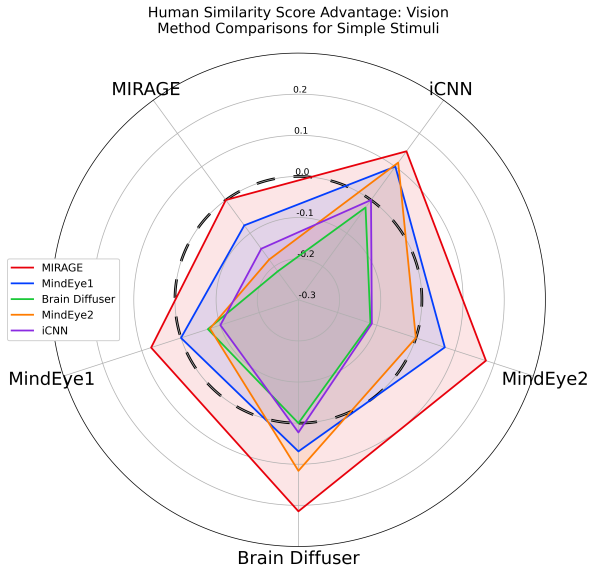

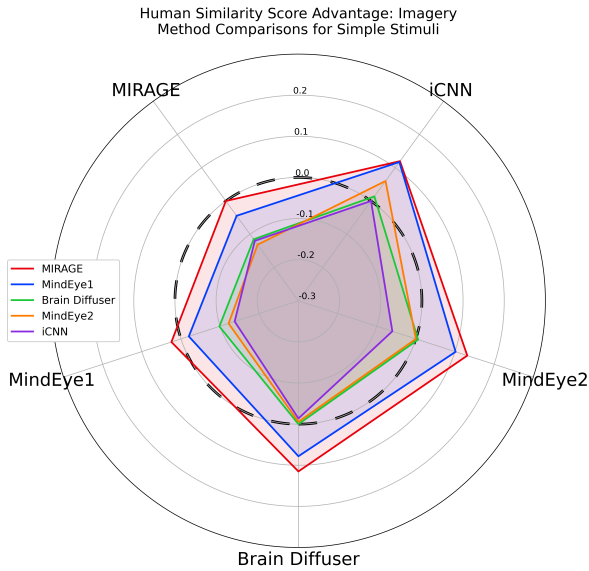

*Figure 1.* Head-to-head human similarity score results for vision reconstructions of the simple stimuli. The Y-axis represents the similarity score advantage, which is the difference in similarity scores between the target method (colored line/polygon) and the alternative method (identified on the radial X-axis). A larger area for the colored polygon indicates a stronger advantage against other methods. The dashed circle at unity represents equal performance between methods.

*Figure 2.* Head-to-head human similarity score results for mental imagery reconstructions of the simple stimuli. The Y-axis represents the similarity score advantage, which is the difference in similarity scores between the target method (colored line/polygon) and the alternative method (identified on the radial X-axis). A larger area for the colored polygon indicates a stronger advantage against other methods. The dashed circle at unity represents equal performance between methods.
